This is not because the hardware is inaccessible, or not yet understood, but because we know what it should do. We use our brains to read, to write, to add, to subtract. These are the simple computations that define the limits of our abilities. In recent years, scientists have found a way to peek inside our mind, and take a peek at these simple brain computations. They can see what sorts of questions we are asking and what answers we are getting. They used the brain scanner to show a child how the mind works, and show what happens when we are exposed to something foreign. They have asked the kids simple math questions, and seen when they fail. They collected DNA from a single cell to predict future behavior. It was, in a word, interesting. And, yesterday, I joined scientists in one of the strangest experiments in our history. I took part in a brain imaging experiment where I was shown words in a foreign language. Beyond the usual video images, the images sent through the coil picked up the voltage from my brain. The image is the nerve impulses, rippling through a small bundle of neurons deep in my brain. The image is hugely inaccurate. The brain is many kilometres across. But even a crude representation gives us some
