What's New In?

The mp3PRO encoder is a lossless audio encoder and decoder that enables you to play at full bitrates without sacrificing audio quality, even at low bitrates (up to 64 kbit/s). The mp3PRO format combines mp3 with Coding Technologies' Spectral Band Replication (SBR) technology. Using SBR avoids the usual bandwidth limitation for low bitrate coding. Thus the mp3PRO format offers full audio bandwidth without annoying artifacts, even at bitrates below 64 kbit/sec. The mp3PRO plugin decodes all audio files, including mp3, VBR and ID3-v2. It has a configuration dialog, which will be displayed after installation. Install: Requirements: Winamp 3.5 or higher. Known problems: Not all plugins are compatible with Winamp 3.5. The plugin is developed for Winamp 3.5 and higher, so it will not work in Winamp 3.3, however Winamp 3.3 is not supported anymore. Please install Winamp 3.5 or higher.

1. Field of the Invention This invention relates to measurement of multiple output signals from a single source.
2. Related Art Lithography processing is used to manufacture various types of devices such as semiconductor, data storage, and flat panel displays. During lithography processing, a substrate such as a semiconductor wafer, data storage disk, or flat panel display, is placed on a wafer support member. A precisely positioned photoresist (resist) coating is applied over the substrate, and the resist coating is then exposed to an image of an integrated circuit, data storage device, or flat panel display formed using one or more lithography masks. The image is typically defined as an array of individually resolved features such as for example, reticles or masks. After the resist is developed, either the exposed or unexposed portions of the resist are removed to allow the underlying layer to be etched, for example, using a plasma etch process. The remaining portions of the resist can then be removed. Lithography exposure tools or scanners use optical or other sensors to measure characteristics of the resist such as thickness. Various optical and other sensors can be used. For example, a reflectometer can be used to measure changes in the thickness of the resist. The reflectometer is positioned below the substrate, and the changes in reflectivity caused by exposure of the resist are sensed. Lithography systems are subject to a number of constraints that complicate the process of analyzing the responses from the various sensors used to measure the thickness of the resist coating. One problem is that the resist coating is often not uniform across the wafer, and thus, the distance from the resist to various sensors can vary. Moreover, the resist coating often varies between the top and bottom of the
